

Delivery Checker

Project Spec — One-Page Overview

The Problem

Companies frequently discover that goods have been damaged or gone missing by the time a shipment reaches its destination, but they have no visibility into what happened during transit. Without a way to verify the condition of the shipment along the route, it is difficult to identify where the damage occurred, who is responsible, and how to prevent it from happening again. Delivery Checker addresses this by giving companies a simple tool for verifying shipment condition from pickup to final delivery.

Key Features

- Employee dispatch to shipment location: assign an employee to travel to the pickup, transit checkpoint, or destination to physically inspect the goods.
- Condition check-ins: the assigned employee logs the state of the shipment (e.g., intact, damaged, missing items) at each checkpoint before the shipment continues.
- Photo/note capture: attach a photo and short note to each check-in as evidence of the shipment's condition at that point.
- Shipment timeline: a simple chronological view showing every check-in from origin to final destination, so a company can see exactly where a problem first appeared.
- Status flag: mark a shipment as "OK" or "Issue Found" at each stage, with an alert sent to the employer when an issue is flagged.
- Final delivery confirmation: a last check confirming the shipment arrived at its destination in the recorded condition.

Constraints (Out of Scope)

- Does not handle route planning, GPS tracking, or live vehicle location — it only records condition at defined checkpoints.
- Does not process payments, invoicing, or insurance claims.
- Does not automatically detect damage from images — condition checks rely on the employee's manual input, not image analysis.
- Does not manage inventory or warehouse stock levels.
- Not a full logistics/fleet management platform — this is a focused inspection and verification tool, not a replacement for existing shipping systems.
